FOREST INSECT SURVEY
MINIDOKA NATIONAL FOREST
1940

by
James C. Evenden
Senior Entomologist

INTRODUCTION

In 1930 a potentially serious and persistent infestation of the mountain pine beetle was present within the lodgepole pine stands of the Cassia Division of the Minidoka National Forest. Although during subsequent years an effort was made to control this infestation, in 1934 it was apparent that the work was not being projected on a scale of sufficient magnitude to accomplish that objective. The failure of this work was believed to have resulted from inadequate surveys which failed to indicate the location and extent of the infestation. To correct this condition a ^othrough survey of all lodgepole stands within the Cassia Division was planned for the fall of 1935. Data obtained from this survey showed that a serious infestation was present in practically all lodgepole pine areas. Control measures were instituted in the fall of 1935 and the spring of 1936, and approximately 21,000 infested trees were treated.

A resurvey of the treated areas in the fall of 1936 indicated a 92 percent reduction in the severity of the 1936 infestation, or 1,626 infested trees, which were treated in 1937. This concentrated action successfully reduced what was considered as a serious situation, and during subsequent years no special survey or control operations have been necessary. The attitude of the forest officers of this forest

toward the forest insect problem has contributed materially towards maintaining this satisfactory condition, for plans were made for the subsequent treatment of all infested trees observed during the course of their field duties. Such consideration to single and isolated groups of infested trees aids in preventing the development of centers of infestation from which more serious outbreaks occur.

THE 1940 SURVEY

Realizing that so-called normal infestations of the mountain pine beetle can and do give rise to destructive outbreaks in a very few years, it was considered advisable to cover again the Cassia Division of the Minidoka with a fairly intensive survey. This project was conducted by the Bureau of Entomology and Plant Quarantine during September. Data were obtained by three men experienced in forest insect surveys, who were directed by James C. Evenden, Forest Insect Laboratory, Coeur d'Alene, Idaho.

This project was instituted on the 3rd of September and completed on the 21st. A total of 62 man-days were used in obtaining data from 1,224 sample acres. Timber survey maps were used to show the location and acreage of the timber patches within each compartment. With this information available the work was directed so as to obtain representative samples from each area.

The Cassia Division is a rather difficult forest area to survey. The lodgepole pine occurs in patches which vary in size from 2 to 150 acres. These patches are scattered throughout a large acreage, which entails a lot of nonproductive travel time. However the terrain is

not unusually rough and there are numerous roads which make most of the areas readily accessible. Although all of the many patches of timber were not sampled, it is believed that the coverage obtained was satisfactory and that the data depict existing conditions.

A summary of the data obtained from each compartment are given in the following tabulations:

BURLEY-OAKLEY WORKING CIRCLE

Harrington Compartment

Number of lodgepole patches -----	3
Total acres -----	145
Number of patches sampled -----	3
Acres of sample strip -----	16.9
Percent of total acreage covered by sample ---	11.65
Number of 1940-attacked trees on strip -----	0

The mature lodgepole pine stands of this area occur in mixture with alpine fir, with some pure border types of the latter species. As a few (5) 1939 attacks of the mountain pine beetle were recorded during the survey, it is entirely possible that there may be a few trees harboring 1940 broods at this time. Regardless of this possibility, the situation is not severe or it would have been revealed by a survey of this intensity.

Coal Pit Compartment

Number of lodgepole patches -----	15
Total acres -----	553
Number of patches sampled -----	13
Acres of sample strip -----	58.5
Percent of total acreage covered by sample ----	10.58
Number of 1940-attacked trees on strip -----	3
Acreage of infested area (Patch D) -----	28
Acres of sample strip in infested patch -----	7
Infested trees per acre of strip -----	.428
Total infested trees in patch -----	12

The small amount of mature lodgepole in this compartment is associated with scattered areas of reproduction.

Porcupines have been active and a large number of trees have been killed and others badly injured by them. The three 1940 and eighteen 1939 attacks of the mountain pine beetle recorded during the survey were in trees that had been injured by porcupines.

Basin Compartment

Number of lodgepole patches -----	22
Total acres -----	420
Number of patches sampled -----	13
Acres of sample strip -----	41
Percent of total acreage covered by sample ----	9.76
Number of 1940-attacked trees on strip -----	0

There are a few fairly large-sized areas of mature pine in this compartment, with the remainder occurring in small patches. Porcupines are active and a number of trees seem to have died from this injury alone.

Sawmill Compartment

Number of lodgepole patches -----	10
Total acres -----	489
Number of patches sampled -----	7
Acres of sample strip -----	71
Percent of total acreage covered by sample -----	14.51
Number of 1940-attacked trees on strip -----	1
Acreage of infested area (Patch B) -----	138
Acres of sample strip in infested patch -----	34
Infested trees per acre of strip -----	.029
Total infested trees in patch -----	4

This compartment is fairly heavily stocked with stands of immature and mature lodgepole pine growing in association with each other. Although there have been some past losses, only one 1940 and four 1939 attacks were recorded. There is considerable porcupine damage, with some trees being killed and others severely weakened.

Although only 7 of the 10 patches were sampled, the data obtained are considered as depicting the status of conditions within the area.

Eckland Compartment

Number of lodgepole patches -----	5
Total acres -----	210
Number of patches sampled -----	5
Acres of sample strip -----	23.3
Percent of total acreage covered by sample -----	11.09
Number of 1940-attacked trees on strip -----	0

Although small in acreage, there is in this compartment considerable lodgepole pine, which occurs in both pure stands and in mixture with alpine fir. Most of the lodgepole is immature, although there are a few small areas of mature trees. No successful 1940 attacks were recorded; however, a few pitched-cut attacks were observed.

Porcupines are killing and weakening many trees.

1st Fork and 2nd Fork Compartment

Number of lodgepole patches -----	17*
Total acres -----	706
Number of patches sampled -----	10
Acres of sample strip -----	55
Percent of total acreage covered by sample ----	7.79
Number of 1940-attacked trees on strip -----	0

* Three of these patches (D, I, and O) are listed as alpine fir (92 acres).

Most of the timber in this area is mature and growing in mixture with alpine fir. Although no 1940 attacks were recorded, there may be a few scattered infested trees.

Lower 3rd Compartment

Number of lodgepole patches -----	6*
Total acres -----	289
Number of patches sampled -----	4
Acres of sample strip -----	17.1
Percent of total acreage covered by sample ----	5.91
Number of 1940-attacked trees on strip -----	0

* One patch (C) of 138 acres listed as alpine fir.

Approximately half of the lodgepole in this compartment can be considered as mature and occurring in mixture with alpine fir. There are some rather large patches of lodgepole pine and a few areas of alpine fir. The terrain is rough, with a number of rather steep canyons.

A few pitched-out attacks were recorded but no successful 1940 attacks.

Upper 3rd Compartment

Number of lodgepole patches -----	16
Total acres -----	909
Number of patches sampled -----	11
Acres of sample strip -----	62.9
Percent of total acreage covered by sample -----	6.91
Number of 1940-attacked trees on strip -----	0

There is not a great deal of lodgepole pine in this small compartment, and most of the stands are immature. There is considerable alpine fir that occurs in pure stands and in mixture with lodgepole pine.

Only 11 of the 16 patches of lodgepole pine were sampled; however, the conditions encountered did not warrant a more intensive coverage.

Trapper Compartment

Number of lodgepole patches -----	18*
Total acres -----	720
Number of patches sampled -----	9
Acres of sample strip -----	57.4
Percent of total acreage covered by sample -----	7.97
Number of 1940-attacked trees on strip -----	7
Acreage of infested area (Patch B) -----	40
Acres of sample strip in infested patch -----	10
Infested trees per acre of strip -----	.7
Total infested trees in patch -----	28

* In addition to these 18 patches of lodgepole there are four patches of alpine fir (F, K, L and P) with an acreage of 193 acres. Five acres of strip were run in these patches.

The terrain of this compartment is rough and steep, but many roads make the timber stands quite accessible. Only 9 of the 18 patches of lodgepole pine were sampled; however, the status of conditions encountered in this area did not seem to warrant a more intensive coverage.

Although some few years ago there were some rather severe losses within this area, only a light 1940 infestation was recorded, which is apparently confined to patch B, an area of some 40 acres. The infested trees were large and apparently overmature.

Badger Gulch Compartment

Number of lodgepole patches -----	11*
Total acres -----	406
Number of patches sampled -----	7
Acres of sample strip -----	37.5
Percent of total acreage covered by sample ----	9.23
Number of 1940-attacked trees on strip -----	0

- * In addition to these areas of lodgepole there are four patches (C, J, M and D) of alpine fir comprising some 155 acres. Twenty-three acres of sample strip were run in these areas.

Although the terrain of this compartment is quite rough with numerous deep draws, the timber stands are made accessible by roads. The lodgepole pine is small and immature but occurs in rather large patches. There are a few areas of pure alpine fir; however considerable is found in association with lodgepole. No 1940 attacks were recorded in this area, and the character of the timber within the unsampled patches did not warrant additional coverage.

Considerable damage is being done to lodgepole pine by porcupine and to aspen by beavers.

Cottonwood Compartment

Number of lodgepole patches -----	22*
Total acres -----	740
Number of patches sampled -----	9
Acres of sample strip -----	36.1
Percent of total acreage covered by sample ----	4.87
Number of 1940-attacked trees on strip -----	17
Acreage of infested area (Patch B) -----	104
Acres of sample strip in infested patch -----	20.3
Infested trees per acre of strip -----	.83
Total infested trees in patch -----	86

* In addition to these 22 patches of lodgepole pine there is one patch of 23 acres that is recorded as alpine fir.

The lodgepole pine stands of this area are mostly small and immature, with some mature trees distributed throughout the patches in the bottom of draws and on the better sites.

The sample strip run in patch B recorded 17 new attacks, which makes a total of 86 for the area. Although the survey did not reveal any further infestation, it is possible that there are a few trees within the patches adjacent to B. This infestation was recorded as being in patch B in the 1st Fork and 2nd Fork Compartment. However in studying the data submitted it is evident that the boundaries between these two units were not observed and that the present listing is correct. Due to the fairly large percent of patch B covered by this survey (19.5%), it is possible that the total number of trees will prove to be somewhat high. This condition results from strips being run in the most susceptible portions of the timber stand in question.

Porcupine work is evident throughout all lodgepole pine patches.

TWIN FALLS WORKING CIRCLE

Goose Creek-Rock Creek Compartment

Number of lodgepole patches -----	37*
Total acres -----	1,363
Number of patches sampled -----	27
Acres of sample strip -----	214.8
Percent of total acreage covered by sample ----	15.75
Number of 1940-attacked trees on strip -----	0

* There are six patches of alpine fir (B, C, W, Y, Co, and Go) containing some 220 acres in addition to the patches of lodgepole.

There is considerable lodgepole pine in this compartment and although most of the stand is immature, there are a number of patches of mature timber. Some scattered 1939 attacks were recorded but none of the present season. Considerable damage to lodgepole is resulting from porcupines.

Lower Rock Creek Compartment

Number of lodgepole patches -----	7
Total acres -----	263
Number of patches sampled -----	6
Acres of sample strip -----	67.1
Percent of total acreage covered by sample ----	25.51
Number of 1940-attacked trees on strip -----	13
Acreage of infested area (Patch A and C) -----	199
Acres of sample strip in infested patch -----	45.2
Infested trees per acre of strip -----	.29
Total infested trees in patch -----	57

This compartment contains the most serious infestation encountered during the survey. The 13 infested trees recorded are concentrated in patches A and C, although it is entirely possible that there are a few scattered infested trees within adjacent areas. The infested trees are large and mature, with many of them showing a previous injury by porcupines. An old kill, possibly 1935 or 1936, has occurred in Wahlstrom Hollow.

McMullen Compartment

Number of lodgepole patches -----	2
Total acres -----	40
Number of patches sampled -----	2
Acres of sample strip -----	7
Percent of total acreage covered by sample ----	17.5
Number of 1940-attacked trees on strip -----	0

The lodgepole pine stands of this area are widely scattered in a number of small patches grouped under A and B. No mountain pine beetle work was recorded for 1939 or 1940. Lodgepole trees are small and scattered throughout patches of reproduction.

Shoshone Compartment

Number of lodgepole patches -----	34
Total acres -----	831
Number of patches sampled -----	25
Acres of sample strip -----	186.6
Percent of total acreage covered by sample ----	22.45
Number of 1940-attacked trees on strip -----	1
Acreage of infested area (Patch A) -----	80
Acres of sample strip in infested patch -----	19.1
Infested trees per acre of strip -----	.052
Total infested trees in patch -----	4

The lodgepole pine stands of this compartment occur in fair-sized patches. Trees are small but apparently in a healthy condition.

Only one successful 1940 attack of the mountain pine beetle was recorded, although there were a few that had been pitched out. Several trees were recorded that had been killed by insects in 1939.

Only 25 of the 34 patches of lodgepole pine were included in the survey; however, the present status of conditions did not warrant a more intensive coverage. A number of patches of timber not shown on the type map were included in the survey.

NEVADA WORKING CIRCLE

Lower Goose Creek Compartment

Number of lodgepole patches -----	18
Total acres -----	462
Number of patches sampled -----	9
Acres of sample strip -----	102.4
Percent of total acreage covered by sample ----	22.16
Number of 1940-attacked trees on strip -----	0

This area is quite rough, with many springs and waterways.

Timber stands are nearly all immature and appear to be in a healthy condition. One 1939 attack was recorded, with porcupines killing the tops of many small trees.

Lower Trout Creek Compartment

Number of lodgepole patches -----	3*
Total acres -----	137
Number of patches sampled -----	3
Acres of sample strip -----	16
Percent of total acreage covered by sample ---	11.69
Number of 1940-attacked trees on strip -----	0

*This includes an extra patch of timber not shown on type map.

The terrain of this compartment is quite rough, with a number of waterways. Timber is small and immature, but apparently in a healthy condition. Alpine fir occurs in large patches and in association with pine. Two 1939 attacks of the mountain pine beetle were recorded.

Beaver Dam Compartment

Number of lodgepole patches -----	4
Total acres -----	80
Number of patches sampled -----	2
Acres of sample strip -----	6
Percent of total acreage covered by sample ----	7.5
Number of 1940-attacked trees on strip -----	0

In this area there is only a small amount of lodgepole pine, which occurs in a few patches near Chalk Springs. No trees were recorded that had been killed by insects during the past few years, although some porcupine work can be seen.

Big Horse Creek Compartment

Number of lodgepole patches -----	4
Total acres -----	433
Number of patches sampled -----	4
Acres of sample strip -----	22
Percent of total acreage covered by sample ----	5.08
Number of 1940-attacked trees on strip -----	0

There is not a great deal of pine in this compartment, and approximately half of the stand can be considered as immature. Timber occurs in small scattered patches.

COST ANALYSIS

Salaries	\$261.50
Subsistence and lodging	65.67
Transportation	30.85
	<u>\$358.02</u>

Man-days	62
Acres of sample strip	1,224
Total lodgepole pine acreage	9,196
Percent of total acreage sampled	13.3
Acres of sample strip per man-day	19.7
Cost per acre of sample strip	\$0.292
Cost of survey per acre of lodgepole pine stand	\$0.038

The cost of this operation may seem a trifle high, but it includes transportation and subsistence of crew from Coeur d'Alene, Idaho, as well as four days accumulated leave.

CONCLUSIONS

Although an infestation of the mountain pine beetle exists within the Cassia Division of the Minidoka National Forest, its status is quite satisfactory at this time. The thorough control operation directed against the 1935 infestation, with the proper maintenance the following season, reduced a serious infestation to a status which has been maintained during the subsequent seasons. As stated, the diligence of local forest officers has contributed materially in protecting the results obtained from control.

In considering the satisfactory condition of the mountain pine beetle infestation which exists within the Cassia Division, one must not disregard the potential danger of such situations. As in this area serious losses have occurred and still more serious damage prevented,

it may be properly assumed that a recurrence of such an outbreak is entirely possible if conditions favorable for such a development prevail. The occurrence of such a condition can be prevented by keeping the lodge-pole pine under proper observation, and the prompt treatment of all small centers of infestation that may develop in the future.

At the present time there are a few infested trees within the Cassia Division, which should be treated. Perhaps this has already been done as in the past by the ranger personnel. This infestation is not serious, but the treatment of these trees can be considered as further insurance against subsequent timber losses. Infested trees are found in the following compartments:

Compartment	Patch	Acres	Trees
Coal Pit	D	28	12
Trapper	B	40	28
Cottonwood	B	104	86
Lower Rock Creek	A & C	199	57
	5	371	183

Although the data as revealed by the survey are given in this summary, it is believed that the number of infested trees may be a trifle high, for in surveying small patches of timber the sample strip often traverses the most susceptible portions of the area, which gives an inflated result.
